## Klausur 1 <br> Berechenbarkeit und Komplexität

23 November 2012
Part 1 NFSM2012
Let $N$ be the nondeterministic finite state machine
$\left(\left\{q_{0}, q_{1}, q_{2}, q_{3}, q_{4}\right\},\{0,1\}, \nu,\left\{q_{0}\right\},\left\{q_{1}, q_{4}\right\}\right)$,
whose transition function $\nu$ is given below.

\section*{| $\mathbf{1}$ |  | no $\quad$ Is $10010011001101 \in L(N) ?$ |
| :--- | :--- | :--- |}

A word $w \in L(N)$ with $|w|>1$ ends either with 11 or 00 , but never with 01 .

| $\mathbf{2}$ | yes | Is $001100 \in L(N)$ ? |
| :--- | :--- | :--- |

Follow the states $q_{0}, q_{3}, q_{2}, q_{0}, q_{1}, q_{2}, q_{4}$.

| $\mathbf{3}$ |  | no |
| :--- | :--- | :--- |
| $\mathbf{4}$ | yes |  |
| $\mathbf{5}$ | yes |  |
| $\mathbf{6}$ | yes |  |

Is $L(N)$ finite?
Is $L(N)=L(r)$ for the regular expression $r=((\varepsilon+1) 001)^{*}(1+00+100)$ ?
Is $\overline{L(N)}$ recursive?
Is there a deterministic finite state machine $M$ with less than 100 states such that $L(M)=L(N)$ ?

According to the subset construction, there must be a DFSM with at most $2^{5}=32$ states.

| $\mathbf{7}$ | yes |  |
| :--- | :--- | :--- |
| Is there a nondeterministic Turing machine $T=(Q, \Gamma, \sqcup,\{0,1\}, \delta, q, F), ~(~$ |  |  | with less than 10 states such that $L(T)=L(N)$ ?

In fact, 7 states are sufficient. We choose $\Gamma=\{0,1, \sqcup\}$, $Q=\left\{q_{0}, \ldots, q_{6}\right\} . p=q_{0}, F=q_{6}$. The transition function is (more or less) given by $\nu$ above. In each step $T$ reads and writes the same character and always moves to the right. If $T$ reads a blank in any of the accepting states $\left\{q_{1}, q_{4}\right\}$ of the NFSM $N$, it goes into the accepting state $q_{6}$ of $T$, if $T$ reads a blank when in one of the states $\left\{q_{0}, q_{2}, q_{3}\right\}$ it goes into the non-exepting state $q_{5}$. The Turing machine $T$ stops in states $q_{5}$ and $q_{6}$.

Does there exists a deterministic finite state machine $D$ such that $L(D)=$ $L(N) \circ \overline{L(N)}$ ?
$L(N)$ and $\overline{L(N)}$ are both regular. Concatenation of two regular languages gives a regular language.

Let

$$
\begin{aligned}
& L_{1}=\left\{a^{m} b^{n} a^{2 m} \mid m, n \in \mathbb{N}, m<1000\right\} \\
& L_{2}=\left\{a^{m} b^{n} a^{2 m} \mid m, n \in \mathbb{N}, n<1000\right\}
\end{aligned}
$$

| $\mathbf{9}$ | yes |  |
| :--- | :--- | :--- | Is there a regular expression $r$ such that $L(r)=L_{1}$ ?

$$
r=b^{*}+a b^{*} a a+a a b^{*} a a a a+\cdots+a^{999} b^{*} a^{1998}
$$

| $\mathbf{1 0}$ |  | no $\quad$ Is there a deterministic finite state machine $M$ such that $L(M)=\{a, b\}^{*} \backslash$ |
| :--- | :--- | :--- | :--- | $L_{2}$ ?

$L_{2}$ is not regular, i.e., its complement $\overline{L_{2}}$ is not regular, either.

| $\mathbf{1 1}$ | yes |  |
| :--- | :--- | :--- |
| $\mathbf{1 2}$ | yes |  |
| $\mathbf{1 3}$ | yes |  |

Is there an enumerator Turing machine $G$ such that $\operatorname{Gen}(G)=L_{1}$ ?
Is there an Turing machine $M$ such that $L(M)=L_{1} \cup L_{2}$ ?
Is there an deterministic finite state machine $D$ such that $L(D)=L_{1} \cap L_{2}$ ?
The language $L_{1} \cap L_{2}$ is finite and thus regular.

Part 3 RecursiveEnumerable6
Let $M$ be a Turing machine with the following property: Whenever $M$ accepts a word, it does so in no more than 1000 steps.

| $\mathbf{1 4}$ | yes | $\quad$ Is $L(M)$ necessarily recursive? |
| :--- | :--- | :--- |

Start $M$ with input $w$ und execute 1000 steps. If $w$ has been accepted then $w \in L(M)$, otherwise $w \notin L(M)$. Therefore, $L(M)$ and $\overline{L(M)}$ are both recursively enumerable.

\section*{| 15 |  | no $\quad$ Is $L(M)$ necessarily finite? |
| :--- | :--- | :--- |}

Let $M=\left(\left\{q_{0}\right\},\{0,1, \sqcup\}, \sqcup,\{0,1\}, \delta, q_{0},\left\{q_{0}\right\}\right)$ where $\delta$ is nowhere defined. Then $L(M)=\Sigma^{*}$.

| 16 | no Let $L$ be a recursively enumerable language. Can it be concluded that |
| :--- | :--- | :--- | $L(M) \cap L$ is recursive?

If $M$ is a Turing machine that accepts everything without any computation, then $L(M)=\Sigma^{*}$ and thus $L(M) \cap L=L$. Thus, if the intersection $L(M) \cap L$ were recursive, it would mean that every recursively enumerable language is recursive. This is clearly not the case.

Part 4 TM2012
Let $M=\left(Q, \Gamma, \sqcup, \Sigma, \delta, q_{0}, F\right)$ be a Turing machine with $Q=\left\{q_{0}, q_{1}, q_{2}\right\}, \Sigma=$ $\{0,1\}, \Gamma=\{0,1, \sqcup\}, F=\left\{q_{2}\right\}$. The transition function

$$
\delta: Q \times \Gamma \rightarrow_{P} Q \times \Gamma \times\{L, R\}
$$

is given by the following table.

| $\delta$ | 0 | 1 | $\sqcup$ |
| :---: | :---: | :---: | :---: |
| $q_{0}$ | $\left(q_{1}, 0, R\right)$ | $\left(q_{0}, 0, R\right)$ | $\left(q_{2}, 1, R\right)$ |
| $q_{1}$ | $\left(q_{0}, 1, R\right)$ | $\left(q_{1}, 0, L\right)$ | - |
| $q_{2}$ | - | - | - |

Furthermore, let $M^{\prime}=\left(Q, \Gamma, \sqcup, \Sigma, \delta^{\prime}, q_{0}, F\right)$ where $\delta^{\prime}$ is (nearly) identical to $\delta$ except for the fact that $\delta^{\prime}\left(q_{1}, 1\right)$ is undefined, i.e., $\delta^{\prime}$ is given by the followig
table.

| $\delta^{\prime}$ | 0 | 1 | $\sqcup$ |
| :---: | :---: | :---: | :---: |
| $q_{0}$ | $\left(q_{1}, 0, R\right)$ | $\left(q_{0}, 0, R\right)$ | $\left(q_{2}, 1, R\right)$ |
| $q_{1}$ | $\left(q_{0}, 1, R\right)$ | - | - |
| $q_{2}$ | - | - | - |

| $\mathbf{1 7}$ | yes | $I s q_{0} 011 \vdash 0 q_{1} 11 \vdash q_{1} 001 \vdash 1 q_{0} 01 \vdash 10 q_{1} 1 \vdash 1 q_{1} 00 \vdash 11 q_{0} 0 \vdash 110 q_{1} \sqcup a$ |
| :--- | :--- | :--- | computation of $M$ ?

| $\mathbf{1 8}$ |  | no $\quad$ Is $011 \in L(M)$ ? |
| :--- | :--- | :--- |

The machine $M$ terminates in the non-accepting state $q_{1}$.

| $\mathbf{1 9}$ | yes |  |
| :---: | :---: | :---: |
| $\mathbf{2 0}$ |  | no |
| $\mathbf{2 1}$ |  | no |
| $\mathbf{2 2}$ |  | no |

Is $L(M)$ a recursively enumerable language?
Is $1101 \in L\left(M^{\prime}\right)$ ?
Is $L\left(M^{\prime}\right)$ a finite set?
Is there a word $w \in \Sigma^{*}$ for which $M$ does not terminate?
The machine goes into state $q_{1}$ only after it has read a 0 and after moving the head right. Thus, if the machine sees a 1 under the head in state $q_{1}$, it is clear that the character left of this 1 is a 0 , i.e. the head will only be moved at most one position to the left and then never come back to the 1 that it writes in state $q_{1}$. Eventually, the head will arrive at a blank and thus the machine stops. Is $L\left(M^{\prime}\right)$ a recursive language?

Obviously, the head is only moved to the right, so eventually, the head will be over a blank and thus the machine terminates.

Part 5 Open2012
((2 points))
Let $N=\left(Q, \Sigma, \delta, q_{0}, F\right)$ be a nondeterministic finite state machine with $Q=$ $\left\{q_{0}, q_{1}, q_{2}, q_{3}\right\}, \Sigma=\{0,1\}, S=\left\{q_{0}\right\}, F=\left\{q_{0}, q_{3}\right\}$, and transition function $\delta$ as given below.

1. Let $X_{i}$ denote the regular expression for the language accepted by $N$ when starting in state $q_{i}$.

Write down an equation system for $X_{0}, \ldots, X_{3}$.
2. Give a regular expression $r$ such that $L(r)=L(N)$ (you may apply Arden's Lemma to the result of 1 ).

$$
\begin{aligned}
X_{0} & =(0+1) X_{1}+1 X_{2}+\varepsilon \\
X_{1} & =(0+1) X_{1}+0 X_{2} \\
X_{2} & =0 X_{3} \\
X_{3} & =\varepsilon \\
r & =\varepsilon+10+(0+1)(0+1)^{*} 00
\end{aligned}
$$
