- 3. A Model of the Client/Server System
- 4. Summary

A Client/Server System

System of one server and two clients.

Three concurrently executing system components.

Server manages a resource.

An object that only one system component may use at any time.

Clients request resource and, having received an answer, use it.

- Server ensures that not both clients use resource simultaneously.
- Server eventually answers every request.

Set of system requirements.

System Implementation

```
Server:
 local given, waiting, sender
begin
 given := 0; waiting := 0
 loop
    sender := receiveRequest()
    if sender = given then
      if waiting = 0 then
        given := 0
      else
        given := waiting; waiting := 0
        sendAnswer(given)
      endif
   elsif given = 0 then
      given := sender
      sendAnswer(given)
   else
     waiting := sender
   endif
 endloop
end Server
```

```
Client(ident):
   param ident
begin
   loop
    ...
   sendRequest()
   receiveAnswer()
   ... // critical region
   sendRequest()
   endloop
end Client
```

Wolfgang Schreiner

Property: mutual exclusion.

- At no time, both clients are in critical region.
 - Critical region: program region after receiving resource from server and before returning resource to server.

• The system shall only reach states, in which mutual exclusion holds.

- Property: no starvation.
 - Always when a client requests the resource, it eventually receives it.
 - Always when the system reaches a state, in which a client has requested a resource, it shall later reach a state, in which the client receives the resource.
- Problem: each system component executes its own program.
 - Multiple program states exist at each moment in time.
 - Total system state is combination of individual program states.
 - Not easy to see which system states are possible.

How can we verify that the system has the desired properties?

1. A Client/Server System

2. Modeling Concurrent Systems

- 3. A Model of the Client/Server System
- 4. Summary

At each moment in time, a system is in a particular state.

- A state $s: Var \rightarrow Val$
 - A state s is a mapping of every system variable x to its value s(x).
 - Typical notation: s = [x = 0, y = 1, ...] = [0, 1, ...].
 - Var ... the set of system variables
 - Program variables, program counters, ...
 - *Val* ... the set of variable values.
- The state space $State = \{s \mid s : Var \rightarrow Val\}$
 - The state space is the set of possible states.
 - The system variables can be viewed as the coordinates of this space.
 - The state space may (or may not) be finite.
 - If |Var| = n and |Val| = m, then $|State| = m^n$.
 - A word of $\log_2 m^n$ bits can represent every state.

A system execution can be described by a path $s_0 \to s_1 \to s_2 \to \dots$ in the state space.

Wolfgang Schreiner

In a sequential system, each state typically determines its successor state.

- The system is deterministic.
 - We have a (possibly not total) transition function F on states.
 - $s_1 = F(s_0)$ means " s_1 is the successor of s_0 ".
- Given an initial state s_0 , the execution is thus determined.

 $\bullet s_0 \rightarrow s_1 = F(s_0) \rightarrow s_2 = F(s_1) \rightarrow \dots$

- A deterministic system (model) is a pair $\langle I, F \rangle$.
 - A set of initial states $I \subseteq State$

Initial state condition $I(s) :\Leftrightarrow s \in I$

• A transition function $F : State \xrightarrow{partial} State$.

- A run of a deterministic system $\langle I, F \rangle$ is a (finite or infinite) sequence $s_0 \rightarrow s_1 \rightarrow \ldots$ of states such that
 - $s_0 \in I$ (respectively $I(s_0)$).
 - $s_{i+1} = F(s_i)$ (for all sequence indices *i*)
 - If s ends in a state s_n , then F is not defined on s_n .

Wolfgang Schreiner

In a concurrent system, each component may change its local state, thus the successor state is not uniquely determined.

- The system is nondeterministic.
 - We have a transition relation *R* on states.
 - $R(s_0, s_1)$ means " s_1 is a (possible) successor of s_0 ".
- Given an initial state s_0 , the execution is not uniquely determined.
 - Both $s_0 \to s_1 \to \ldots$ and $s_0 \to s_1' \to \ldots$ are possible.
- A non-deterministic system (model) is a pair $\langle I, R \rangle$.
 - A set of initial states (initial state condition) $I \subseteq State$.
 - A transition relation $R \subseteq State \times State$.
- A run s of a nondeterministic system $\langle I, R \rangle$ is a (finite or infinite) sequence $s_0 \rightarrow s_1 \rightarrow s_2 \dots$ of states such that
 - $s_0 \in I$ (respectively $I(s_0)$).
 - $R(s_i, s_{i+1})$ (for all sequence indices *i*).
 - If s ends in a state s_n , then there is no state t such that $R(s_n, t)$.

Derived Notions

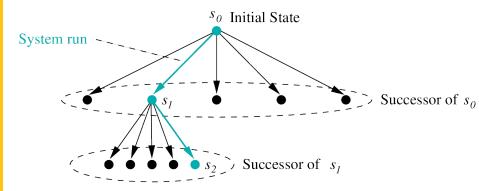

- Successor and predecessor:
 - State t is a (direct) successor of state s, if R(s, t).
 - State *s* is then a predecessor of *t*.
 - A finite run $s_0 \rightarrow \ldots \rightarrow s_n$ ends in a state which has no successor.
- Reachability:
 - A state t is reachable, if there exists some run $s_0 \rightarrow s_1 \rightarrow s_2 \rightarrow \ldots$ such that $t = s_i$ (for some i).
 - A state *t* is unreachable, if it is not reachable.

Not all states are reachable (typically most are unreachable).

The transitions of a system can be visualized by a graph.

The nodes of the graph are the reachable states of the system.

Wolfgang Schreiner

Examples

6 1. Automata

Fig. 1.1. A model of a watch

of \mathcal{A}_{e3} correspond to the possible counter values. Its transitions reflect the possible actions on the counter. In this example we restrict our operations to increments (inc) and decrements (dec).

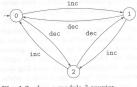

Fig. 1.2. A_{c3} : a modulo 3 counter

B.Berard et al: "Systems and Software Verification", 2001.

Examples

■
$$R_C(i, i')$$
 : \Leftrightarrow $inc(i, i') \lor dec(i, i')$.
■ $inc(i, i')$: \Leftrightarrow if $i < 2$ then $i' = i + 1$ else $i' = 0$.
■ $dec(i, i')$: \Leftrightarrow if $i > 0$ then $i' = i - 1$ else $i' = 2$.

Compose *n* components S_i to a concurrent system *S*.

- State space $State := State_0 \times \ldots \times State_{n-1}$.
 - *State*_i is the state space of component *i*.
 - State space is Cartesian product of component state spaces.
 - Size of state space is product of the sizes of the component spaces.

Example: three counters with state spaces \mathbb{N}_2 and \mathbb{N}_3 and \mathbb{N}_4 .

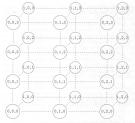

Fig. 1.9. The states of the product of the three counters

B.Berard et al: "Systems and Software Verification", 2001.

What are the initial states I of the composed system?

$$\blacksquare Set I := I_0 \times \ldots \times I_{n-1}.$$

- *I_i* is the set of initial states of component *i*.
- Set of initial states is Cartesian product of the sets of initial states of the individual components.
- Predicate $I(s_0, \ldots, s_{n-1}) :\Leftrightarrow I_0(s_0) \land \ldots \land I_{n-1}(s_{n-1}).$
 - *I_i* is the initial state condition of component *i*.
 - Initial state condition is conjunction of the initial state conditions of the components on the corresponding projection of the state.

Size of initial state set is the product of the sizes of the initial state sets of the individual components.

Which transitions can the composed system perform?

- Synchronized composition.
 - At each step, every component must perform a transition.
 - R_i is the transition relation of component *i*.

$$\begin{array}{l} R(\langle s_0,\ldots,s_{n-1}\rangle,\langle s_0',\ldots,s_{n-1}'\rangle) :\Leftrightarrow \\ R_0(s_0,s_0') \wedge \ldots \wedge R_{n-1}(s_{n-1},s_{n-1}'). \end{array}$$

Asynchronous composition.

. . .

At each moment, every component may perform a transition.

- At least one component performs a transition.
- Multiple simultaneous transitions are possible

• With *n* components, $2^n - 1$ possibilities of (combined) transitions.

$$\begin{array}{c} R(\langle s_0, \ldots, s_{n-1} \rangle, \langle s'_0, \ldots, s'_{n-1} \rangle) : \Leftrightarrow \\ (R_0(s_0, s'_0) \wedge \ldots \wedge s_{n-1} = s'_{n-1}) \lor \end{array}$$

$$(s_0 = s'_0 \land \ldots \land R_{n-1}(s_{n-1}, s'_{n-1})) \lor$$

$$(R_0(s_0,s_0')\wedge\ldots\wedge R_{n-1}(s_{n-1},s_{n-1}'))$$

Wolfgang Schreiner

Example

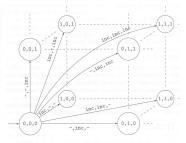

System of three counters with state space \mathbb{N}_2 each.

Synchronous composition:

 $[0,0,0] \leftrightarrows [1,1,1]$

Asynchronous composition:

B.Berard et al: "Systems and Software Verification", 2001.

Simplified view of asynchronous execution.

- At each moment, only one component performs a transition.
 - Do not allow simultaneous transition $t_i | t_i$ of two components *i* and *j*.
 - **Transition** sequences t_i ; t_j and t_j ; t_i are possible.
 - All possible interleavings of component transitions are considered.
 - Nondeterminism is used to simulate concurrency.
 - Essentially no change of system properties.
 - With n components, only n possibilities of a transition.

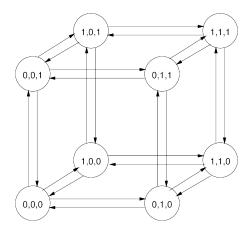

$$R(\langle s_0, s_1, \dots, s_{n-1} \rangle, \langle s'_0, s'_1, \dots, s'_{n-1} \rangle)) \Leftrightarrow (R_0(s_0, s'_0) \land s_1 = s'_1 \land \dots \land s_{n-1} = s'_{n-1}) \lor (s_0 = s'_0 \land R_1(s_1, s'_1) \land \dots \land s_{n-1} = s'_{n-1}) \lor \dots (s_0 = s'_0 \land s_1 = s'_1 \land \dots \land R_{n-1}(s_{n-1}, s'_{n-1})).$$

Interleaving model (respectively a variant of it) suffices in practice.

Example

System of three counters with state space \mathbb{N}_2 each.

Digital Circuits

Synchronous composition of hardware components.

• A modulo 8 counter $C = \langle I_C, R_C \rangle$.

State := $\mathbb{N}_2 \times \mathbb{N}_2 \times \mathbb{N}_2$.

$$I_C(v_0, v_1, v_2) :\Leftrightarrow v_0 = v_1 = v_2 = 0.$$

$$\begin{array}{l} R_{C}(\langle v_{0}, v_{1}, v_{2} \rangle, \langle v_{0}', v_{1}', v_{2}' \rangle) :\Leftrightarrow \\ R_{0}(v_{0}, v_{0}') \land \\ R_{1}(v_{0}, v_{1}, v_{1}') \land \\ R_{2}(v_{0}, v_{1}, v_{2}, v_{2}'). \end{array}$$

$$\begin{aligned} &R_0(v_0, v_0') :\Leftrightarrow v_0' = \neg v_0. \\ &R_1(v_0, v_1, v_1') :\Leftrightarrow v_1' = v_0 \oplus v_1. \\ &R_2(v_0, v_1, v_2, v_2') :\Leftrightarrow v_2' = (v_0 \wedge v_1) \oplus v_2. \end{aligned}$$

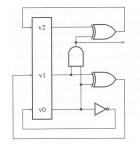

Figure 2.1 Synchronous modulo 8 counter.

Edmund Clarke et al: "Model Checking", 1999.

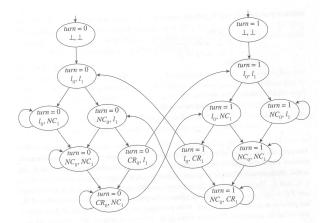

Asynchronous composition of software components with shared variables.

■ A mutual exclusion program $M = \langle I_M, R_M \rangle$. State := $PC \times PC \times \mathbb{N}_2$. // shared variable $I_M(p, q, turn) :\Leftrightarrow p = I_0 \land q = I_1$. $R_M(\langle p, q, turn \rangle, \langle p', q', turn' \rangle) :\Leftrightarrow$ $(P(\langle p, turn \rangle, \langle p', turn' \rangle) \land q' = q) \lor (Q(\langle q, turn \rangle, \langle q', turn' \rangle) \land p' = p)$. $P(\langle p, turn \rangle, \langle p', turn' \rangle) :\Leftrightarrow$ $(p = I_0 \land p' = NC_0 \land turn' = turn) \lor$ $(p = NC_0 \land p' = CR_0 \land turn = 0 \land turn' = turn) \lor$ $(p = CR_0 \land p' = I_0 \land turn' = 1)$. $Q(\langle q, turn \rangle, \langle q', turn' \rangle) :\Leftrightarrow$ $(q = I_1 \land q' = NC_1 \land turn' = turn) \lor$ $(q = CR_1 \land q' = CR_1 \land turn' = turn) \lor$

Wolfgang Schreiner

Concurrent Software

Edmund Clarke et al: "Model Checking", 1999.

Model guarantees mutual exclusion.

Wolfgang Schreiner

Transition relations are typically described in a particular form.

- $R(s,s') :\Leftrightarrow P(s) \wedge s' = F(s).$
 - Guard condition *P* on state in which transition can be performed.
 - If P(s) holds, then there exists some s' such that R(s, s').
 - Transition function *F* that determines the successor of *s*.
 - F is defined for all states for which P(s) holds:
 - $F : \{s \in State : P(s)\} \rightarrow State.$

Examples:

Assignment: $l: x := e; m : \dots$ $R(\langle pc, x, y \rangle, \langle pc', x', y' \rangle) :\Leftrightarrow pc = l \land (x' = e \land y' = y \land pc' = m).$ Wait statement: l: wait $P(x, y); m : \dots$ $R(\langle pc, x, y \rangle, \langle pc', x', y' \rangle) :\Leftrightarrow$ $pc = l \land P(x, y) \land (x' = x \land y' = y \land pc' = m).$ Guarded assignment: $l: P(x, y) \rightarrow x := e; m : \dots$ $R(\langle pc, x, y \rangle, \langle pc', x', y' \rangle) :\Leftrightarrow$ $pc = l \land P(x, y) \land (x' = e \land y' = y \land pc' = m).$

Most programming language commands can be translated into this form.

Wolfgang Schreiner

How to model an asynchronous system without shared variables where the components communicate/synchronize by exchanging messages?

- Given a label set $Label = Int \cup Ext \cup \overline{Ext}$.
 - Disjoint sets Int and Ext of internal and external labels.
 - "Anonymous" label $_{-} \in Int$.
 - Complementary label set $\overline{L} := \{\overline{l} : l \in L\}.$
- A labeled system is a pair $\langle I, R \rangle$.
 - Initial state condition $I \subseteq State$.
 - Labeled transition relation $R \subseteq Label \times State \times State$.
- A run of a labeled system $\langle I, R \rangle$ is a (finite or infinite) sequence $s_0 \xrightarrow{l_0} s_1 \xrightarrow{l_1} \ldots$ of states such that
 - $s_0 \in I$.
 - $R(I_i, s_i, s_{i+1})$ (for all sequence indices *i*).
 - If s ends in a state s_n , there is no label l and state t s.t. $R(l, s_n, t)$.

Compose a set of *n* labeled systems $\langle I_i, R_i \rangle$ to a system $\langle I, R \rangle$.

- State space $State := State_0 \times \ldots \times State_{n-1}$.
- Initial states $I := I_0 \times \ldots \times I_{n-1}$.
 - $I(s_0,\ldots,s_{n-1}):\Leftrightarrow I_0(s_0)\wedge\ldots\wedge I_{n-1}(s_{n-1}).$
- Transition relation

$$\begin{split} & R(I, \langle s_i \rangle_{i \in \mathbb{N}_n}, \langle s'_i \rangle_{i \in \mathbb{N}_n}) \Leftrightarrow \\ & (I \in Int \land \exists i \in \mathbb{N}_n : \\ & R_i(I, s_i, s'_i) \land \forall k \in \mathbb{N}_n \backslash \{i\} : s_k = s'_k) \lor \\ & (I = _ \land \exists I \in Ext, i \in \mathbb{N}_n, j \in \mathbb{N}_n : \\ & R_i(I, s_i, s'_i) \land R_j(\overline{I}, s_j, s'_j) \land \forall k \in \mathbb{N}_n \backslash \{i, j\} : s_k = s'_k). \end{split}$$

Either a component performs an internal transition or two components simultaneously perform an external transition with complementary labels.

Communication by Message Passing

• Two labeled systems $\langle I_0, R_0 \rangle$ and $\langle I_1, R_1 \rangle$. State₀ = State₁ = PC × N, Internal := {A, B}, External := {M, N}. $I_0(p, i) :\Leftrightarrow p = a_0 \land i \in \mathbb{N}; I_1(q, j) :\Leftrightarrow q = b_0.$ $R_0(I, \langle p, i \rangle, \langle p', i' \rangle) :\Leftrightarrow$ $(I = \overline{M} \land p = a_0 \land p' = a_1 \land i' = i) \lor$ $(I = N \land p = a_1 \land p' = a_2 \land i' = j) \lor //$ illegal! $(I = A \land p = a_2 \land p' = a_0 \land i' = i + 1).$ $R_1(I, \langle q, j \rangle, \langle q', j' \rangle) :\Leftrightarrow$ $(I = M \land q = b_0 \land q' = b_1 \land j' = i) \lor //$ illegal! $(I = B \land q = b_1 \land q' = b_2 \land j' = j + 1) \lor$ $(I = \overline{N} \land q = b_2 \land q' = b_0 \land j' = j).$

Wolfgang Schreiner

Composition of
$$\langle I_0, R_0 \rangle$$
 and $\langle I_1, R_1 \rangle$ to $\langle I, R \rangle$.

$$State = (PC \times \mathbb{N}) \times (PC \times \mathbb{N}).$$

$$I(p, i, q, j) :\Leftrightarrow p = a_0 \land i \in \mathbb{N} \land q = b_0.$$

$$\begin{array}{l} R(I, \langle p, i, q, j \rangle, \langle p', i', q', j' \rangle) : \Leftrightarrow \\ (I = A \land (p = a_2 \land p' = a_0 \land i' = i + 1) \land (q' = q \land j' = j)) \lor \\ (I = B \land (p' = p \land i' = i) \land (q = b_1 \land q' = b_2 \land j' = j + 1)) \lor \\ (I = _- \land (p = a_0 \land p' = a_1 \land i' = i) \land (q = b_0 \land q' = b_1 \land j' = i)) \lor \\ (I = _- \land (p = a_1 \land p' = a_2 \land i' = j) \land (q = b_2 \land q' = b_0 \land j' = j)). \end{array}$$

Problem: state relation of each component refers to local variable of other component (variables are shared).

Example (Revised)

 $\begin{array}{rl} 0 ::: \ \mbox{loop} & & \\ & a_0 : \ \mbox{send}(i) & & \\ & a_1 : \ i := \ \mbox{receive}() & & || \\ & & a_2 : \ i := \ i + 1 & \\ & \ \mbox{end} & \end{array}$

• Two labeled systems $\langle I_0, R_0 \rangle$ and $\langle I_1, R_1 \rangle$.

$$\begin{split} & \text{External} := \{M_k : k \in \mathbb{N}\} \cup \{N_k : k \in \mathbb{N}\}.\\ & R_0(I, \langle p, i \rangle, \langle p', i' \rangle) :\Leftrightarrow\\ & (I = \overline{M_i} \land p = a_0 \land p' = a_1 \land i' = i) \lor \\ & (\exists k \in \mathbb{N} : I = N_k \land p = a_1 \land p' = a_2 \land i' = k) \lor \\ & (I = A \land p = a_2 \land p' = a_0 \land i' = i + 1).\\ & R_1(I, \langle q, j \rangle, \langle q', j' \rangle) :\Leftrightarrow\\ & (\exists k \in \mathbb{N} : I = M_k \land q = b_0 \land q' = b_1 \land j' = k) \lor \\ & (I = B \land q = b_1 \land q' = b_2 \land j' = j + 1) \lor \\ & (I = \overline{N_j} \land q = b_2 \land q' = b_0 \land j' = j). \end{split}$$

Encode message value in label.

Wolfgang Schreiner

Composition of
$$\langle I_0, R_0 \rangle$$
 and $\langle I_1, R_1 \rangle$ to $\langle I, R \rangle$.

$$\mathit{State} = (\mathit{PC} imes \mathbb{N}) imes (\mathit{PC} imes \mathbb{N}).$$

$$I(p, i, q, j) :\Leftrightarrow p = a_0 \wedge i \in \mathbb{N} \wedge q = b_0.$$

$$\begin{split} & R(I, \langle p, i, q, j \rangle, \langle p', i', q', j' \rangle) : \Leftrightarrow \\ & (I = A \land (p = a_2 \land p' = a_0 \land i' = i + 1) \land (q' = q \land j' = j)) \lor \\ & (I = B \land (p' = p \land i' = i) \land (q = b_1 \land q' = b_2 \land j' = j + 1)) \lor \\ & (I = _ \land \exists k \in \mathbb{N} : k = i \land \land \\ & (p = a_0 \land p' = a_1 \land i' = i) \land (q = b_0 \land q' = b_1 \land j' = k)) \lor \\ & (I = _ \land \exists k \in \mathbb{N} : k = j \land \\ & (p = a_1 \land p' = a_2 \land i' = k) \land (q = b_2 \land q' = b_0 \land j' = j)). \end{split}$$

Logically equivalent to previous definition of transition relation.

- 1. A Client/Server System
- 2. Modeling Concurrent Systems
- 3. A Model of the Client/Server System
- 4. Summary

Asynchronous composition of three components $Client_1$, $Client_2$, Server.

- Client_i: State := $PC \times \mathbb{N}_2 \times \mathbb{N}_2$.
 - Three variables *pc*, *request*, *answer*.
 - *pc* represents the program counter.
 - *request* is the buffer for outgoing requests.
 - Filled by client, when a request is to be sent to server.
 - *answer* is the buffer for incoming answers.
 - Checked by client, when it waits for an answer from the server.

• Server: State := $(\mathbb{N}_3)^3 \times (\{1,2\} \rightarrow \mathbb{N}_2)^2$.

- Variables given, waiting, sender, rbuffer, sbuffer.
- No program counter.
 - We use the value of *sender* to check whether server waits for a request (*sender* = 0) or answers a request (*sender* \neq 0).
- Variables given, waiting, sender as in program.
- *rbuffer(i)* is the buffer for incoming requests from client *i*.
- *sbuffer*(*i*) is the buffer for outgoing answers to client *i*.

External Transitions

- $Ext := \{REQ_1, REQ_2, ANS_1, ANS_2\}.$
 - Transition labeled *REQ_i* transmits a request from client *i* to server.
 - Enabled when request $\neq 0$ in client *i*.
 - Effect in client *i*: request' = 0.
 - Effect in server: rbuffer'(i) = 1.
 - Transition labeled ANS_i transmits an answer from server to client i
 - Enabled when $sbuffer(i) \neq 0$.
 - Effect in server: sbuffer'(i) = 0.
 - Effect in client *i*: answer' = 1.

The external transitions correspond to system-level actions of the communication subsystem (rather than to the user-level actions of the client/server program).

The Client

$$\begin{array}{l} \textbf{Client system } C_i = \langle IC_i, RC_i \rangle.\\ state := PC \times \mathbb{N}_2 \times \mathbb{N}_2.\\ Int := \{R_i, S_i, C_i\}.\\ \hline IC_i(pc, request, answer) :\Leftrightarrow\\ pc = R \wedge request = 0 \wedge answer = 0.\\ RC_i(I, \langle pc, request, answer \rangle,\\ \langle pc', request', answer \rangle) :\Leftrightarrow\\ (I = R_i \wedge pc = R \wedge request = 0 \wedge\\ pc' = S \wedge request' = 1 \wedge answer' = answer) \lor\\ (I = S_i \wedge pc = S \wedge answer \neq 0 \wedge\\ pc' = C \wedge request' = request \wedge answer' = 0) \lor\\ (I = C_i \wedge pc = C \wedge request = 0 \wedge\\ pc' = R \wedge request' = 1 \wedge answer' = answer) \lor \end{array}$$

Wolfgang Schreiner

The Server

Server system $S = \langle IS, RS \rangle$. State := $(\mathbb{N}_3)^3 \times (\{1,2\} \rightarrow \mathbb{N}_2)^2$. Int := $\{D1, D2, F, A1, A2, W\}$.

$$\begin{array}{l} IS(given, waiting, sender, rbuffer, sbuffer) :\Leftrightarrow \\ given = waiting = sender = 0 \land \\ rbuffer(1) = rbuffer(2) = sbuffer(1) = sbuffer(2) = 0 \end{array}$$

$$\begin{split} &RS(I, \langle given, waiting, sender, rbuffer, sbuffer \rangle, \\ & \langle given', waiting', sender', rbuffer', sbuffer' \rangle) :\Leftrightarrow \\ & \exists i \in \{1,2\} : \\ & (I = D_i \land sender = 0 \land rbuffer(i) \neq 0 \land \\ & sender' = i \land rbuffer'(i) = 0 \land \\ & U(given, waiting, sbuffer) \land \\ & \forall j \in \{1,2\} \backslash \{i\} : U_j(rbuffer)) \lor \\ & \ddots \end{split}$$

$$U(x_1,\ldots,x_n):\Leftrightarrow x'_1 = x_1 \land \ldots \land x'_n = x_n.$$

$$U_j(x_1,\ldots,x_n):\Leftrightarrow x'_1(j) = x_1(j) \land \ldots \land x'_n(j) = x_n(j).$$

Server: local given, waiting, sender begin given := 0; waiting := 0 loop D: sender := receiveRequest() if sender = given then if waiting = 0 then F: given := 0 else A1: given := waiting; waiting := 0 sendAnswer(given) endif elsif given = 0 then A2: given := sender sendAnswer(given) else W: waiting := sender endif endloop end Server

 $U(given, rbuffer, sbuffer)) \lor$

 $\exists i \in \{1,2\}$:

$$(I = REQ_i \land rbuffer'(i) = 1 \land U(given, waiting, sender, sbuffer) \land \forall j \in \{1, 2\} \backslash \{i\} : U_j(rbuffer)) \lor$$

$$\begin{array}{l} (I = \overline{ANS_i} \land sbuffer(i) \neq 0 \land \\ sbuffer'(i) = 0 \land \\ U(given, waiting, sender, rbuffer) \land \\ \forall j \in \{1, 2\} \backslash \{i\} : U_j(sbuffer)). \end{array}$$

```
Server:
  local given, waiting, sender
begin
  given := 0; waiting := 0
  loop
D: sender := receiveRequest()
    if sender = given then
      if waiting = 0 then
F:
        given := 0
      else
A1:
        given := waiting;
        waiting := 0
        sendAnswer(given)
      endif
    elsif given = 0 then
A2:
      given := sender
      sendAnswer(given)
    else
W:
      waiting := sender
    endif
  endloop
end Server
```

Communication Channels

We also model the communication medium between components.

- **Bounded channel** Channel_{*i*,*j*} = ($ICH, RCH_{i,j}$).
 - Transfers message from component with address i to component j.
 - May hold at most N messages at a time (for some N).

Sequence of values of type *Value*.

•
$$Ext := {SEND_{i,j}(m) : m \in Value} \cup {RECEIVE_{i,j}(m) : m \in Value}.$$

By SEND_{i,j}(m), channel receives from sender i a message m destined for receiver j; by RECEIVE_{i,j}(m), channel forwards that message.

 $ICH(queue) :\Leftrightarrow queue = \langle \rangle.$

 $RCH_{i,j}(I, queue, queue') :\Leftrightarrow$

 $\exists m \in Value$:

$$(I = SEND_{i,j}(m) \land |queue| < N \land queue' = queue \circ \langle m \rangle) \lor \\ (I = \overline{RECEIVE}_{i,j}(m) \land |queue| > 0 \land queue = \langle m \rangle \circ queue')$$

Wolfgang Schreiner

Server receives address 0.

- Label REQ_i is renamed to $RECEIVE_{i,0}(R)$.
- Label $\overline{ANS_i}$ is renamed to $\overline{SEND_{0,i}(A)}$.
- Client *i* receives address *i* ($i \in \{1, 2\}$).
 - Label $\overline{REQ_i}$ is renamed to $\overline{SEND_{i,0}(R)}$.
 - Label ANS_i is renamed to $RECEIVE_{0,i}(A)$.
- System is composed of seven components:
 - Server, Client₁, Client₂.
 - *Channel*_{0,1}, *Channel*_{1,0}.
 - Channel_{0,2}, Channel_{2,0}.

Also channels are active system components.

- 2. Modeling Concurrent Systems
- 3. A Model of the Client/Server System

4. Summary

Summary

- A system is described by
 - its (finite or infinite) state space,
 - the initial state condition (set of input states),
 - the transition relation on states.
- State space of composed system is product of component spaces.
 - Variable shared among components occurs only once in product.
- System composition can be
 - synchronous: conjunction of individual transition relations.
 - Suitable for digital hardware.
 - **asynchronous**: disjunction of relations.
 - Interleaving model: each relation conjoins the transition relation of one component with the identity relations of all other components.
 - Suitable for concurrent software.
- Message passing systems may be modeled by using labels:
 - Synchronize transitions of sender and receiver.
 - Carry values to be transmitted from sender to receiver.
