Turing Machine Model

- The machine is always in one of a **finite set of states**.
 - The machine starts its execution in a fixed start state.
- An **infinite tape** holds at its beginning the input word.
 - Tape is read and written and arbitrarily moved by the machine.
- The machine proceeds in a sequence of state **transitions**.
 - Machine reads symbol, overwrites it, and moves tape head left or right.
 - The symbol read and the current state determine the symbol written, the move direction, and the next state.
- If the machine cannot make another transition, it **terminates**.
 - The machine signals whether it is in a final state.

If the machine terminates in a final state, the input word is **accepted**.

Turing Machines

Turing Machine $M = (Q, \Gamma, \sqcup, \Sigma, \delta, q_0, F)$:

- The **state set** Q , a finite set of **states**.
- A **tape alphabet** Γ , a finite set of **tape symbols**.
- The **blank symbol** $\sqcup \in \Gamma$.
- An **input alphabet** $\Sigma \subseteq \Gamma \setminus \{\sqcup\}$.
- The **transition function** $\delta : Q \times \Gamma \rightarrow Q \times \Gamma \times \{L, R\}$,
 - $\delta(q, x) = (q', x', L/R)$... M reads in state q symbol x , goes to state q' , writes symbol x' , and moves the tape head left/right.
- The **start state** $q_0 \in Q$
- A set of **final states (accepting states)** $F \subseteq Q$.

The crucial difference to an automaton is the infinite tape that can be arbitrarily moved and written.

Example

$M = (Q, \Gamma, \sqcup, \Sigma, \delta, q_0, F)$
 $Q = \{q_0, q_1, q_2, q_3, q_4\}$
 $\Gamma = \{\sqcup, 0, 1, X, Y\}$
 $\Sigma = \{0, 1\}$
 $F = \{q_4\}$

δ	\sqcup	0	1	X	Y
q_0	—	(q_1, X, R)	—	—	(q_3, Y, R)
q_1	—	$(q_1, 0, R)$	(q_2, Y, L)	—	(q_1, Y, R)
q_2	—	$(q_2, 0, L)$	—	(q_0, X, R)	(q_2, Y, L)
q_3	(q_4, \sqcup, R)	—	—	—	(q_3, Y, R)
q_4	—	—	—	—	—

Machine accepts every word of form $0^n 1^n$ (replacing it by $X^n Y^n$).

Turing Machine Simulators

For instance, <http://math.hws.edu/TMCM/java/xTuringMachine>.

Wolfgang Schreiner

<http://www.risc.jku.at>

6/28

Generalized Turing Machines

- Infinite tape in **both directions**.
 - Can be simulated by a machine whose tape is infinite in one direction.
- **Multiple** tapes.
 - Can be simulated by a machine with a single tape.
- **Nondeterministic** transitions.
 - We can simulate a nondeterministic M by a deterministic M' .
 - Let r be the maximum number of "choices" that M can make.
 - M' operates with 3 tapes.
 - Tape 1 holds the input (tape is only read).
 - M' writes to tape 2 all finite sequences of numbers $1, \dots, r$.
 - First all sequences of length 1, then all of length 2, etc.
 - After writing sequence $s_1 s_2 \dots s_n$ to tape 2, M' simulates M on tape 3.
 - M' copies the input to tape 3 and performs at most n transitions.
 - In transition i , M attempts to perform choice s_i .
 - If choice i is not possible or M terminates after n transitions in a non-accepting state, M' continues with next sequence.
 - If M terminates in accepting state, M' accepts the input.

Every generalized Turing machine can be simulated by the core form.

Turing Machine Configurations

- **Configuration** $a_1 \dots a_k q a_{k+1} \dots a_m$:
 - q : the current state of M .
 - a_{k+1} : the symbol currently under the tape head.
 - $a_1 \dots a_k$: the portion of the tape left to the tape head.
 - $a_{k+2} \dots a_m$: the portion right to the head (followed by $\sqcup \dots$).
- **Move relation:** $a_1 \dots a_k q a_{k+1} \dots a_m \vdash b_1 \dots b_l p b_{l+1} \dots b_m$
 If M is a situation described by the left configuration, it can make a transition to the situation described by the right configuration.
 - $a_i = b_i$ for all $i \neq k+1$ and one of the following:
 - $l = k+1$ and $\delta(q, a_{k+1}) = (p, b_l, R)$,
 - $l = k-1$ and $\delta(q, a_{k+1}) = (p, b_{l+2}, L)$.
- **Extended move relation:** $c_1 \vdash^* c_2$
 M can make in an arbitrary number of moves a transition from the situation described by configuration c_1 to the one described by c_2 .

$$c_1 \vdash^0 c_2 : \Leftrightarrow c_1 = c_2$$

$$c_1 \vdash^{i+1} c_2 : \Leftrightarrow \exists c : c_1 \vdash^i c \wedge c \vdash c_2$$

$$c_1 \vdash^* c_2 : \Leftrightarrow \exists i \in \mathbb{N} : c_1 \vdash^i c_2$$

The Language of a Turing Machine

- The **language** $L(M)$ of Turing machine $M = (Q, \Gamma, \sqcup, \Sigma, \delta, q_0, F)$:
 The set of all inputs that drive M from its initial configuration to a configuration with a final state such that from this configuration no further move is possible:

$$L(M) := \left\{ w \in \Sigma^* \mid \begin{array}{l} \exists a, b \in \Gamma^*, q \in Q : q_0 w \vdash^* a q b \wedge q \in F \\ \wedge \neg \exists a', b' \in \Gamma^*, q' \in Q : a q b \vdash a' q' b' \end{array} \right\}$$
- L is a **recursively enumerable language**:
 - There exists a Turing machine M such that $L = L(M)$.
- L is a **recursive language**:
 - There exists a Turing machine M such that $L = L(M)$ and M terminates for every possible input.

Every recursive language is recursively enumerable; as we will see, the converse does not hold.

Recursiv. Enumerable/Recursive Languages

Theorem: L is recursive, if and only if both L and its complement \bar{L} are recursively enumerable.

Proof \Rightarrow : Let L be a recursive. Since by definition L is recursively enumerable, it remains to be shown that also \bar{L} is recursively enumerable.
 Since L is recursive, there exists a Turing machine M such that M halts for every input w : if $w \in L$, then M accepts w ; if $w \notin L$, then M does not accept w . With the help of M , we can construct the following M' with $L(M') = \bar{L}$:

```
function M'(w):
  case M(w) of
    yes: return no
    no: return yes
  end case
end function
```

Recursiv. Enumerable/Recursive Languages

Proof \Leftarrow : Let L be such that both L and \bar{L} are recursively enumerable. We show that L is recursive. Since L is r.e., there exists M such that $L = L(M)$ and M halts for $w \in L$ with $M(w) = \text{yes}$. Since \bar{L} is r.e., there exists \bar{M} with $\bar{L} = L(\bar{M})$ and \bar{M} halts for $w \in \bar{L}$ with $\bar{M}(w) = \text{yes}$. We can thus construct M'' with $L(M'') = L$ that always halts:

```
function M''(w):
  parallel
    begin
      if M(w) = yes then
        return yes
      end if
      loop forever
    end
  begin
    if M-bar(w) = yes then
      return no
    end if
    loop forever
  end
end parallel
end function
```

Closure of Recursive Languages

Let L, L_1, L_2 be recursive languages. Then also

- the complement \bar{L} ,
- the union $L_1 \cup L_2$,
- the intersection $L_1 \cap L_2$

are recursive languages.

Proof by construction of the corresponding Turing machines.

2. Recognizing Languages

3. Generating Languages

4. Computing Functions

5. The Church-Turing Thesis

Enumerators

Turing machine $M = (Q, \Gamma, \sqcup, \emptyset, \delta, q_0, F)$ with special symbol $\# \in \Gamma$.

- M is an **enumerator**, if M has an additional **output tape** on which
 - M moves its tape head only to the right, and
 - M writes only symbols different from \sqcup .
- The **generated language** $Gen(M)$ of enumerator M is the set of all words that M eventually writes on its output tape.
 - The end of each word is marked by a trailing $\#$.

M may run forever and thus $Gen(M)$ may be infinite.

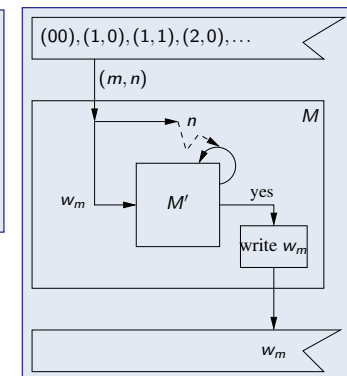

Recognizing versus Generating Languages

Theorem: L is recursively enumerable, if and only if there exists some enumerator M such that $L = Gen(M)$.

Proof \Rightarrow : Let L be recursively enumerable, i.e., $L = L(M')$ for some M' . We construct enumerator M such that $L = Gen(M)$.

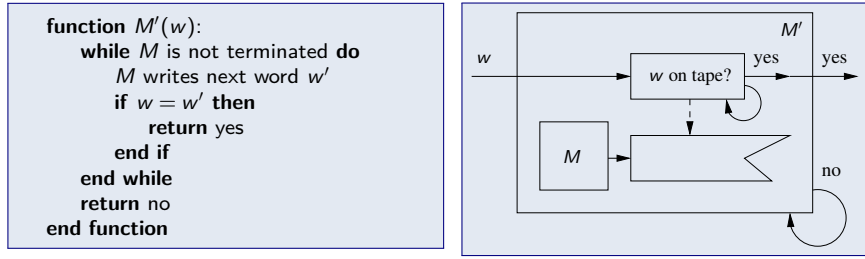

```
procedure M:
  loop
    produce next (m, n) on working tape
    if M'(w_m) = yes in at most n steps then
      write w_m to output tape
    end if
  end loop
end procedure
```

Recognizing versus Generating Languages

Proof \Leftarrow : Let L be such that $L = \text{Gen}(M)$ for some enumerator M . We show that there exists some Turing machine M' such that $L = L(M')$.

Recognizing is possible, if and only if generating is possible.

1. Turing Machines
2. Recognizing Languages
3. Generating Languages
4. Computing Functions
5. The Church-Turing Thesis

Functions

Take binary relation $f \subseteq A \times B$.

- $f : A \rightarrow B$: f is a **total function** from A to B .
 - For every $a \in A$, there is **exactly one** $b \in B$ such that $(a, b) \in f$.
- $f : A \rightarrow_p B$: f is a **partial function** from A to B .
 - For every $a \in A$, there is **at most one** $b \in B$ such that $(a, b) \in f$.
- Auxiliary notions:

$$\begin{aligned} \text{domain}(f) &:= \{a \mid \exists b : (a, b) \in f\} \\ \text{range}(f) &:= \{b \mid \exists a : (a, b) \in f\} \\ f(a) &:= \text{such } b : (a, b) \in f \end{aligned}$$

Every total function $f : A \rightarrow B$ is a partial function $f : A \rightarrow_p B$; every partial function $f : A \rightarrow_p B$ is a total function $f : \text{domain}(f) \rightarrow B$.

Functions

- Let $f : \Sigma^* \rightarrow_p \Gamma^*$ where $\sqcup \notin \Sigma \cup \Gamma$.
 - f is a function over words in some alphabets.
- f is **Turing computable**, if there exists a Turing machine M such that
 - for input w (i.e. initial tape content $w \sqcup \dots$), M terminates in a final state, if and only if $w \in \text{domain}(f)$;
 - for input w , M terminates in a final state with output w' (i.e. final tape content $w' \sqcup \dots$), if and only if $w' = f(w)$.
- **Not every function $f : \Sigma^* \rightarrow_p \Gamma^*$ is Turing computable:**
 - The set of all Turing machines is countably infinite: all machines can be ordered in a single list (in the alphabetic order of their definitions).
 - The set of all functions $\Sigma^* \rightarrow_p \Gamma^*$ is more than countably infinite (Cantor's diagonalization argument).
 - Consequently, there are more functions than Turing machines.

M computes f , if M terminates for arguments in the domain of f with output $f(a)$ and does not terminate for arguments outside the domain.

Example

We show that natural number subtraction is Turing computable.

- Subtraction \ominus on \mathbb{N} :

$$m \ominus n := \begin{cases} m - n & \text{if } m \geq n \\ 0 & \text{else} \end{cases}$$

- Unary representation of $n \in \mathbb{N}$:

$$\underbrace{000\dots 0}_{n \text{ times}} \in L(0^*)$$

- Input $00 \sqcup 0$ shall lead to output 0.
 - $2 \ominus 1 = 1$.

Idea: replace every pair of 0 in m and n by \sqcup .

Example (Contd)

$M = (Q, \Gamma, \Sigma, \delta, q_0, F)$
 $Q = \{q_0, \dots, q_6\}$
 $\Sigma = \{0\}, \Gamma = \{0, 1, \sqcup\}, F = \{q_6\}$

δ	0	1	\sqcup
q_0	(q_1, \sqcup, R)	(q_5, \sqcup, R)	(q_5, \sqcup, R)
q_1	$(q_1, 0, R)$	$(q_2, 1, R)$	$(q_2, 1, R)$
q_2	$(q_3, 1, L)$	$(q_2, 1, R)$	(q_4, \sqcup, L)
q_3	$(q_3, 0, L)$	$(q_3, 1, L)$	(q_0, \sqcup, R)
q_4	$(q_4, 0, L)$	(q_4, \sqcup, L)	$(q_6, 0, R)$
q_5	(q_5, \sqcup, R)	(q_5, \sqcup, R)	(q_6, \sqcup, R)
q_6	—	—	—

- In q_0 , the leading 0 is replaced by \sqcup .
- In q_1 , M searches for the next \sqcup and replaces it by a 1.
- In q_2 , M searches for the next 0 and replaces it by 1, then moves left.
- In q_3 , M searches for previous \sqcup , moves right and starts from begin.
- In q_4 , M has found a \sqcup instead of 0 and replaces all previous 1 by \sqcup .
- In q_5 , n is (has become) 0; the rest of the tape is erased.
- In q_6 , the computation successfully terminates.

Example (Contd)

- $2 \ominus 1 = 1$:

$q_0 00 \sqcup 0 \vdash \sqcup q_1 0 \sqcup 0 \vdash \sqcup 0 q_1 \sqcup 0 \vdash \sqcup 0 1 q_2 0$
 $\vdash \sqcup 0 q_3 1 1 \vdash \sqcup q_3 0 1 1 \vdash q_3 \sqcup 0 1 1 \vdash \sqcup q_0 0 1 1$
 $\vdash \sqcup \sqcup q_1 1 1 \vdash \sqcup \sqcup 1 q_2 1 \vdash \sqcup \sqcup 1 1 q_2 \vdash \sqcup \sqcup 1 q_4 1$
 $\vdash \sqcup \sqcup q_4 1 \vdash \sqcup q_4 \vdash \sqcup 0 q_6$

- $1 \ominus 2 = 0$:

$q_0 0 \sqcup 0 0 \vdash \sqcup q_1 \sqcup 0 0 \vdash \sqcup 1 q_2 0 0 \vdash \sqcup q_3 1 1 0$
 $\vdash q_3 \sqcup 1 1 0 \vdash \sqcup q_0 1 1 0 \vdash \sqcup \sqcup q_5 1 0 \vdash \sqcup \sqcup \sqcup q_5 0$
 $\vdash \sqcup \sqcup \sqcup \sqcup q_5 \vdash \sqcup \sqcup \sqcup \sqcup \sqcup q_6$

For $m > n$, leading blanks still have to be removed.

Turing Computability

Theorem: $f : \Sigma^* \rightarrow \Gamma^*$ is Turing computable, if and only if

$$L_f := \{(a, b) \in \Sigma^* \times \Gamma^* \mid a \in \text{domain}(f) \wedge b = f(a)\}$$

is recursively enumerable.

Proof \Rightarrow : Since $f : \Sigma^* \rightarrow \Gamma^*$ is Turing computable, there exists a Turing machine M which computes f . To show that L_f is r.e., we construct M' with $L(M') = L_f$:

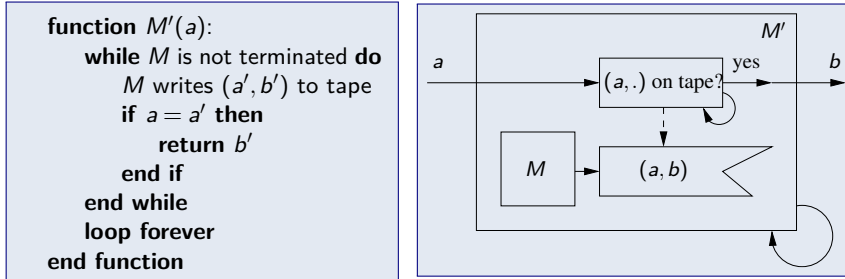

```
function M'(a, b):
  b' ← M(a)
  if b' = b then
    return yes
  else
    return no
  end if
end function
```

Turing Computability

Proof \Leftarrow : Since L_f is recursively enumerable, there exists an enumerator M with $Gen(M) = L_f$. We construct the following Turing machine M' which computes f :

Computing is possible, if and only if recognizing is possible.

1. Turing Machines

2. Recognizing Languages

3. Generating Languages

4. Computing Functions

5. The Church-Turing Thesis

Algorithms

Computer science is based on algorithms.

Compute as follows the greatest common divisor of two natural numbers m, n that are not both 0:

1. If $m = 0$, the result is n .
2. If $n = 0$, the result is m .
3. If $m > n$, subtract n from m and continue with step 1.
4. Otherwise subtract m from n and continue with step 1.

```

Euklid(↓ m, ↓ n, ↑ r):
  while m ≠ 0 ∧ n ≠ 0 do
    if m > n
      then m ← m - n
      else n ← n - m
    if m = 0
      then r ← n
      else r ← m
  end Euklid.
        
```

What is an “algorithm” and what is computable by an algorithm?

The Church-Turing Thesis

Church-Turing Thesis: Every problem that is solvable by an algorithm (in an intuitive sense) is solvable by a Turing machine. Thus the set of intuitively computable functions is identical with the set of Turing computable functions.

- Replaces fuzzy notion “algorithm” by precise notion “Turing machine”.
- Unprovable thesis, exactly because the notion “algorithm” is fuzzy.
- Substantially validated, because many different computational models have no more computational power than Turing machines.
 - Random access machines, loop programs, recursive functions, goto programs, λ -calculus, rewriting systems, grammars, ...

Turing machines represent the most powerful computational model known, but there are many other equally powerful (“Turing complete”) models.
